

# LISA Pathfinder Status

S. Vitale

1<sup>st</sup> ELISA Consortium meeting

# Layout of the talk

- Status of LTP
- Status of Mission
- Status of operation preparation

# Status of LTP

- GRS most sensitive items:
  - Test-masses
  - Launch lock
  - Test-mass release
  - Discharging
  - Electrode housing
- Optical metrology
  - Diodes
  - End-to-end tests
- Integration

# Test-masses

- 2×Flight test-masses (2 kg, 46 mm)
- Very high density homogeneity ( $\ll 1\mu\text{m}$  pores)
- CoG at geometrical center within  $\pm 2\mu\text{m}$
- Magnetic susceptibility at  $\chi = -(2.3 \pm 0.2) \times 10^{-5}$
- Magnetic moment  $< 4\text{ nAm}^2$

# Qualification model under test (TRR and DRB successful)

# Test mass release

- New test-campaign with 1 kg test-mass

Differential optical shadow sensor

1 kg TM mock-up

Tip pitch positioner

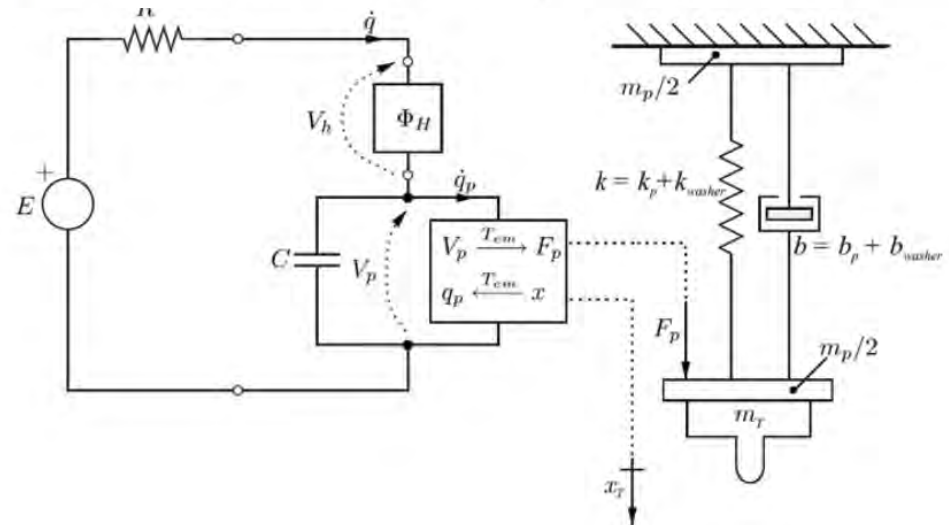

yaw/pitch adjustable TM rear blocking system

# The transferred momentum

- Maximum momentum now stable ( $15 \mu\text{Ns}$ ).
- Results with 1 kg mass similar to those with 100 g

# Extrapolating to flight

- Momentum measurement give force vs. elongation of adhered contact
- Extrapolated to flight via an electromechanical model
- Extrapolation ( $<4 \mu\text{N}$  s) compliant with factor 3 margin

# Test with true GPRM

- Lab is preparing for test with EM of GPRM. Likely at end of 2013 (due to availability of GPRM)
- Results of test do not require extrapolation
- Test with uncoated test-mass-pin contact, likely to have lower adhesion, to be tested soon.

# Discharging

- Issue: bipolar discharge shown critical in torsion pendulum experiments
- Root causes:
  1. Photo-emissivity of surfaces variable by one order of magnitude or more depending on adsorbate
  2. Light aimed at test-mass (electrodes) is reflected off and ends on the electrodes (test-mass) extracting unwanted electrons from there
- Mitigation approach
  1. Stabilize photo-emissivity by appropriate treatment
  2. Redirect light with proper micro-mirrors

# Stabilization of photoemissivity

- The main steps
  1. Plasma-clean surfaces before integration
    - Plasma-cleaning (oxygen) process under qualification. No damage to surfaces. Hydrocarbon adsorbate reduced by a factor 3-4
  2. Clean surfaces by UV light in oxygen atmosphere. Light is shone through standard UV fibers but with more powerful lamp
    - Qualification on samples started, lamp procured, photoemissivity measurement contract issued
  3. Bake-out surfaces after integration (already planned)

# Light re-direction

- Light to electrode housing redirected to minimize stray reflection toward the test-mass
- Performed by means of a very small mirror on the tip of the fiber
- Two designs under prototyping

# Light re-direction

- After measurement of true UV reflectivity predicted effectiveness of method has been reduced

	Baseline		Retro-Fit	
Discharge Direction	$\Delta\dot{Q}_{TM}^+$	$\Delta\dot{Q}_{TM}^-$	$\Delta\dot{Q}_{TM}^+$	$\Delta\dot{Q}_{TM}^-$
No DC bias voltages	*	1.88	*	3.71
DC bias voltages to support positive discharge rates	*	–	*	–
DC bias voltages to support negative discharge rates	–	10.65	–	13.62

- However surface treatment is expected to reduce  $|\Delta Q| < 3$

# Discharging

- GRS after bake-out has shown bipolar discharge in all cases, though only with properly selected electrode bias configuration
- Re-grabbing test-mass has been shown to leave it in an acceptable charging status

# The Electrode Housing

- GRS electrode housing FM1
- Vibration qualification performed

# Failure of one of the brazed joints

- Failure casted doubt over the brazing process
- NRB was not able to identify a way forward with acceptable schedule impact
- A “Tiger Team” formed. Schedule is driving requirement. Report due on October 24. Various options identified
- October 30 a review board meets in Rome and decides the way forward to minimize schedule impact

# Leaks from the TT

- A method of inspection of the joints may be available
- A possible process for refurbishing brazing joints without disassembling faces also identified but still to be assessed

# Optical Bench

- Optical bench n.3 used in thermal test now baseline for flight

L

# Optical Bench

- Outstanding vibration qualification went well but:
  - Harness caused debris
  - While inspecting InGAs photodiodes for debris, damage was found in harness epoxy and debris inside harness
- Problems considered non critical

# end-to-end tests

- Two relevant tests have been performed:
  - An end to end test of interferometry performance (already mentioned)
  - A closed-loop test of the satellite

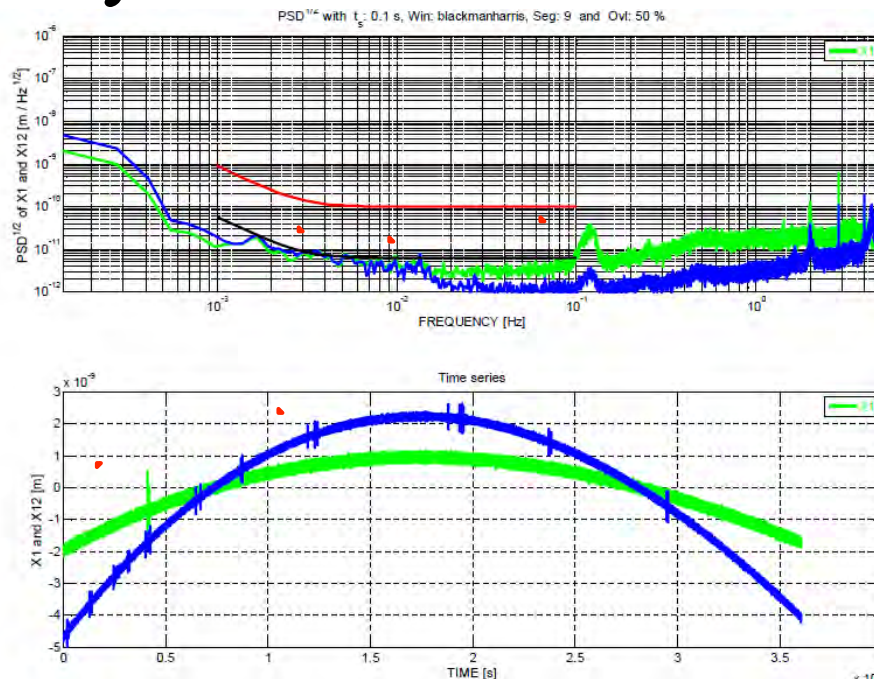

# LTP electronic and optical units

# end-to-end tests

- During both tests, various “features” or non compliances were discovered.
- These are being assessed for impact on performance and possible fix. Quite a few have been already fixed

This document is the property of Astrium. It shall not be communicated to third parties without prior written agreement. Its content shall not be disclosed.

# GRS EQM integration

- A qualification test of the entire assembly including caging
- Qualification test in Feb 13

# ISH EQM Integration

# Integration schedule

- Integration and testing is the schedule bottleneck
- GRS requires 15 month after repair of EH
- LCA 7 more months
- A group has been set-up to scrutinize requirement to check if test, alignment requirements, integration environment requirements.. can be relaxed to make up some time.

## Subject: Decision on the change of Micro-Propulsion System baseline for LISA Pathfinder

In November 2011 the LISA Pathfinder Micro-Propulsion System Review (MPSR) Board reviewed the status of the Caesium FEEP development tests and of the alternative Cold Gas system. The Board recommended (cf. Board Report DG-IR/2011/109/KL) continuing the testing of the FEEPs on unit and assembly level (TUVT and TAET respectively). In parallel, as a backup, the Board recommended to proceed with and complete the design work for the cold gas system, and to initiate the procurement of the long lead items. The overall status should be presented to the Board not later than April 2012. Such report was released in due time by the LPF Project (cf. SRE-PN/17498-12-GR), including the criteria to reach a decision on the MPS for LPF.

This memorandum summarizes the status reached at the present time, and introduces the LPF Project decision to select the cold gas micro-propulsion system as baseline and to discontinue further development work of the FEEP system within the context of the LISA Pathfinder project.

- Cold gas developed for Gaia better than requirements
- Now selected as baseline in place of FEEPs

# A functional test on the entire chain

Unexpected features observed in the response ADT20033 to S/C guidance signals. The 3<sup>rd</sup> injection is using a fade-in and fade-out feature that was not requested. The 5<sup>th</sup> injection of the Inv01001 (matched stiffness section) has wrong frequency.

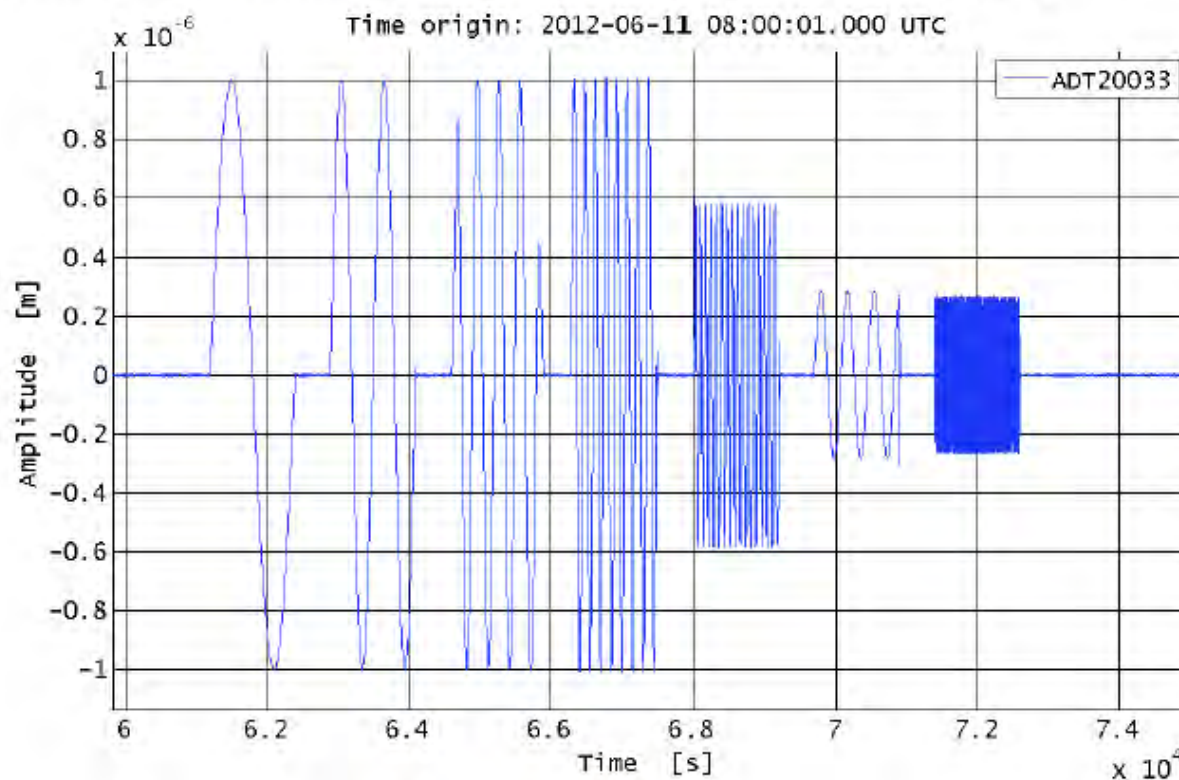

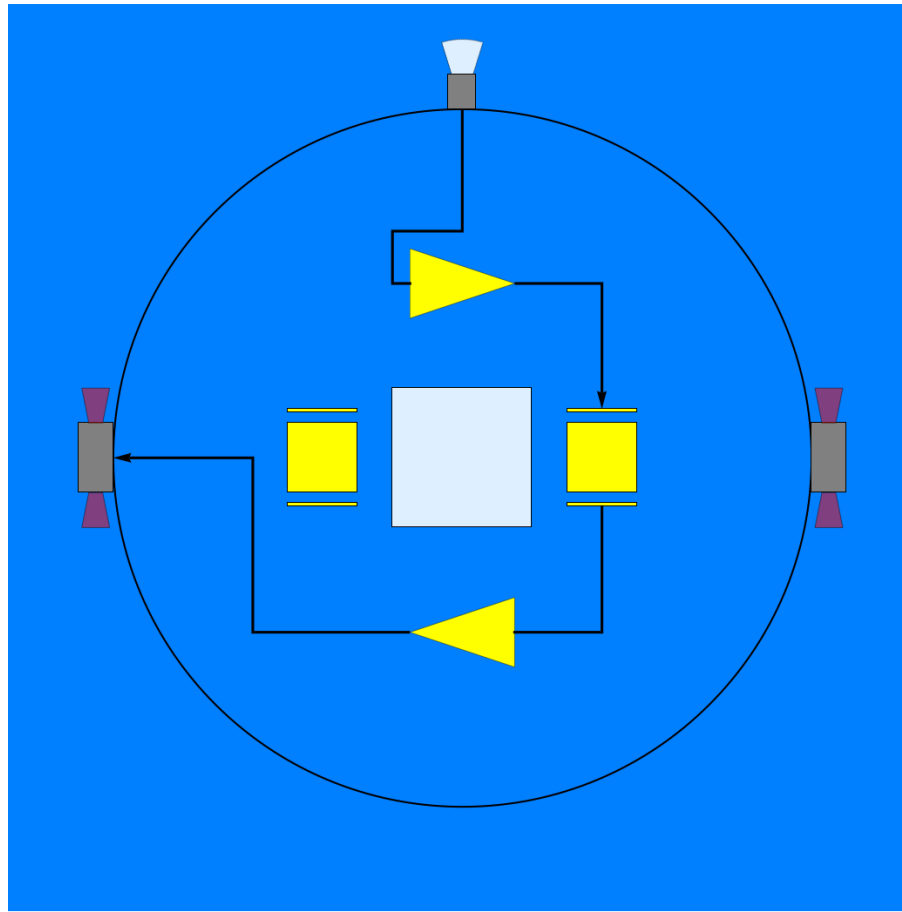

Figure 10 ADT20033 for the Inv01001 investigation, matched stiffness. The 3<sup>rd</sup> and 5<sup>th</sup> injections show unexpected features.

# A true experiment

- Strong correlation found between main channel  $\Delta x$ , and force commanded on test-masses along  $y$
- These forces are used to control the attitude of S/C

# Limitation of LPF method

- Star Trackers are used to stabilize rotation
  - Star Tracker pushes test-masses with differential force  $\Delta f_y = f_{y1} - f_{y2}$  to restore orientation.
  - Spacecraft/optical bench follows using thrusters.
- *Star Tracker are very noisy: up to  $100 \mu\text{rad}/\sqrt{\text{Hz}}$  @  $0.1 \text{ mHz}$*

# Cross-coherence between $\Delta x$ and $f_{y1} - f_{y2}$ .

# De-correlation by subtraction in the time domain $\Delta x' = \Delta x - \alpha(f_{v1} - f_{v2})$

# Summary

- A few item with low criticalities
- Micro-thrusters nominally on critical path just for procurement reasons.
- *EH on critical path because quick fix is still outstanding. October 30 we'll know more*
- All remaining sectors are doing well.
